1 Multilevel Multilingual

“This curious world which we inhabit is more wonderful than it is convenient...”
(Thoreau, 1975)

“Mathematics is my secret. My secret weakness. I feel like a stubborn, helpless fool in the middle of a problem. Trapped and crazed. Also, thrilled.” (Schanen, 2021)

1.1 Introduction

Below, I describe the use of [Stata](#) (StataCorp, 2023), [R](#) (Bates et al., 2015; R Core Team, 2023), and [Julia](#) (Bates, 2024; Bezanson et al., 2017) to estimate multilevel models.

All of these software packages can estimate multilevel models and can visualize relationships in the data. However, there are substantial differences between the different packages: Stata is proprietary *for cost* software, which is very well documented and very intuitive. While it costs money to purchase Stata, the price is often very reasonable for academic and educational use. R is *free* open source software which is less intuitive, but there are many excellent resources for learning R. There is often a cost associated with purchasing books and other materials for learning R, which sometimes feels like it offsets the fact that R is free. Julia is newer open source software, also *free*, and ostensibly much faster than either Stata or R, which may be an important advantage when running multilevel models with very large data sets. At this point in time, both Stata and R feel much more *stable* than Julia which is still evolving software.

While any of these software packages can be used for learning and estimating multilevel models, I will offer my own opinion—based upon 15 years of teaching multilevel models at the doctoral level—that Stata offers the quickest pathway for learning the basic and advanced uses of multilevel models. I also believe the intuitive nature of Stata syntax contributes to accurate and replicable work in this area.

Table 1.1: Software for Multilevel Modeling

Software	Cost	Ease of Use
Stata	some cost	learning curve, but very intuitive for both multilevel modeling and graphing.

Software	Cost	Ease of Use
R	free	learning curve: intuitive for multilevel modeling; but steeper learning curve for graphing (<code>ggplot</code>).
Julia	free	steep learning curve in general: steep learning curve for multilevel modeling; and very steep learning curve for graphing. Graphics libraries are very much under development and in flux.

💡 Results Will Vary Somewhat

Estimating multilevel models is a complex endeavor. The software details of how this is accomplished are beyond the purview of this book. Suffice it to say that across different software packages there will be differences in estimation routines, resulting in some numerical differences in the results provided by different software packages. Substantively speaking, however, results should agree across software.

💡 Multi-Line Commands

Sometimes I have written commands out over multiple lines. I have done this for especially long commands, but have also sometimes done this simply for the sake of clarity. The different software packages have different approaches to multi-line commands.

1. By default, *Stata* ends a command at the end of a line. If you are going to write a multi-line command you should use the `///` line continuation characters.
2. *R* is the software that most naturally can be written using multiple lines, as *R* commands are usually clearly encased in parentheses `()` or continued with `+` signs.
3. Like *Stata*, *Julia* expects commands to end at the end of a line. If you are going to write a multi-line command, all commands except for the last line should end in a character that clearly indicates continuation, like a `+` sign. An alternative is to encase the entire *Julia* command in an outer set of parentheses `()`.

💡 Running Statistical Packages in Quarto

I used Quarto (Allaire et al., 2024) (<https://quarto.org/>) to create this Appendix. Quarto is a programming and publishing environment that can run multiple programming languages, including *Stata*, *R* and *Julia*, and that can write to multiple output formats including HTML, PDF, and MS Word. To run *Stata*, I used the `Statamarkdown` library (Hemken, 2023) in *R* to connect *Stata* to Quarto. Quarto has a built in connection to *R*,

and runs R without issue. To run Julia, I used the `JuliaCall` library (Li, 2019) in R to connect Quarto to Julia.

Of course, each of these programs can be run by itself, if you have them installed on your computer.

1.2 The Data

Datasets

The examples use the `simulated_multilevel_data.dta` and `simulated_multilevel_longitudinal_data.dta` files.

Here is a [direct link](#) to download the cross-sectional data.

Here is a [direct link](#) to download the longitudinal data.

4	55.05
3	49.81

1.3 An Introduction To Equations and Syntax

To explain statistical syntax for each software, I consider the general case of a multilevel model with dependent variable y , independent variables \mathbf{x} and \mathbf{z} , clustering variable `group`, and a random slope for \mathbf{x} . i is the index for the person, while j is the index for the group.

$$y = \beta_0 + \beta_1 x_{ij} + \beta_2 z_{ij} + u_{0j} + u_{1j} \times x_{ij} + e_{ij} \quad (1.1)$$

1.3.1 Stata

In Stata `mixed`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
mixed y x z || group: x
```

1.3.2 R

In R `lme4`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
library(lme4)

lmer(y ~ x + z + (1 + x || group), data = ...)
```

1.3.3 Julia

In Julia `MixedModels`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
using MixedModels

fit(MixedModel, @formula(y ~ x + z + (1 + x | group)), data)
```

2 Statistical Workflows

2.1 Statistical Software Is Best Run Using a Script

Many statistical workflows—whatever the statistical package being used—follow the same conceptual pattern.

Figure 2.1: A Common Statistical Workflow

Increasingly, we want to think about workflows that are

- **documentable, transparent, and auditable:** We have a record of what we did if we want to double check our work, clarify a result, or develop a new project with a similar process. We, or others, can find the inevitable errors in our work, **and correct them**.
- **replicable:** Others can replicate our findings with the same or new data.

- **scalable:** We are developing a process that can be as easily used with *thousands* or *millions* of rows of data as it can with *ten* rows of data. We are developing a process that can be easily repeated if we are *constantly getting new or updated data*, e.g. getting new data every week, or every month.

2.2 Scripts

For most statistical workflows, we will often want to write a script or code. Data analysis scripts can be stored in a Quarto document (Allaire et al., 2024) as they are in this Appendix, or every statistical package has its own unique format for storing scripts as a text file: in Stata, scripts are stored in `.do` files; in R, scripts are stored in `.R` files, and in Julia, scripts are stored in `.jl` files.

2.3 Script Flow

A good practice when writing a script, is to have a script that begins with the raw data, moves through any necessary re-coding or cleaning of the data, generates descriptive statistics, generates the appropriate multivariate results, and then generates any necessary visualizations.

2.4 Storing Statistical Data

It is usually best to store quantitative data in a statistical format such as R (`.Rdata`), or Stata (`.dta`), or even a text format such as `.csv`. Spreadsheets are likely to be a bad tool for storing quantitative data.

2.5 It Is Possible To Use Multiple Statistical Packages

While this Appendix focuses on the use of each individual statistical package on its own, it is certainly possible to use multiple statistical packages as part of the same workflow. For example, one might employ Stata to carry out data management tasks, and then possibly use R to run a multilevel model with a more complicated multilevel structure, such as a cross-classified model, or Julia to more quickly run a model with a large data.

2.6 Good Statistical Workflows Require Safe Workspaces

It is also *very important* to be aware that good complex workflows are *highly iterative* and *highly collaborative*. Good complex workflows require a *safe workspace* in which team members feel free to admit their own errors, and help with others' mistakes in a non-judgmental fashion. Such a *safe environment* is necessary to build an environment where the *overall error rate* is low.

2.7 Good Statistical Workflows Require Patience And Can Be Psychologically Demanding

Developing a good documented and auditable workflow that is implemented in code requires a lot of patience, and often, **many iterations**. Working through these many iterations can be psychologically demanding. It is important to remember that careful attention to getting the details right early in the research process, while sometimes tiring and frustrating, will pay large dividends later on when the research is reviewed, presented, published and read.

2.8 Good Statistical Workflows Often Allow Multiple Principled Ways Forward

One of my most recent ideas about statistical workflows is that there are certainly *wrong* decisions that one can make with data.

For example, I would not want to write the paper that says that smoking prevents lung cancer, nor would I want to write a paper saying physical punishment is good for children.

That being said, I think there are often *multiple principled ways forward*.

Often the key is not so much to make the 100% correct decision, but to make one of *several possible principled decisions*.

Then after making a *principled decision*, one is *transparent* and *thorough* about describing the decision that one made.

For example, in implementing a multilevel analysis, I would have many choices: I could estimate only a random intercept; estimate one or more random slopes; or estimate all possible random slopes. The random effects could be correlated or uncorrelated. I could estimate only main effects, or could estimate interactions of several variables. Each of these would be a different, yet principled, approach to analyzing the data.

In science and statistics, we often want an answer that provides one clear direction. Instead, I'm increasingly convinced that the best science (and teaching!) often involves engaging in

open discussion about the multiple possible alternatives, and then choosing one principled solution, and being transparent about its implementation.

3 Descriptive Statistics

3.1 Descriptive Statistics

3.1.1 Stata

```
use simulated_multilevel_data.dta // use data
```

We use `summarize` for *continuous* variables, and `tabulate` for *categorical* variables.

```
summarize outcome warmth physical_punishment HDI
```

```
tabulate identity
```

```
tabulate intervention
```

Variable	Obs	Mean	Std. dev.	Min	Max
-----+-----					
outcome	3,000	52.43327	6.530996	29.60798	74.83553
warmth	3,000	3.521667	1.888399	0	7
physical_p~t	3,000	2.478667	1.360942	0	5
HDI	3,000	64.76667	17.24562	33	87

hypothetica			
l identity			
group			
variable	Freq.	Percent	Cum.
-----+-----			
0	1,507	50.23	50.23
1	1,493	49.77	100.00
-----+-----			
Total	3,000	100.00	

recieved interventio	n	Freq.	Percent	Cum.
0	1,547	51.57	51.57	
1	1,453	48.43	100.00	
Total	3,000	100.00		

3.1.2 R

```
library(haven) # read data in Stata format

df <- read_dta("simulated_multilevel_data.dta")
```

R's descriptive statistics functions rely heavily on whether a variable is a *numeric* variable, or a *factor* variable. Below, I convert two variables to factors (`factor`) before using `summary`¹ to generate descriptive statistics.

```
df$country <- factor(df$country)

df$identity <- factor(df$identity)

df$intervention <- factor(df$intervention)

summary(df)
```

```

country      HDI      family      id      identity
1      : 100  Min.   :33.00  Min.   : 1.00  Length:3000  0:1507

3.1.3 Julia

```
using Tables, MixedModels, MixedModelsExtras, StatFiles, DataFrames, CategoricalArrays, DataAPI

df = DataFrame(load("simulated_multilevel_data.dta"))
```

Similarly to R, Julia relies on the idea of *variable type*. I use `transform` to convert the appropriate variables to *categorical* variables.

```
@transform!(df, :country = categorical(:country))

@transform!(df, :identity = categorical(:identity))

@transform!(df, :intervention = categorical(:intervention))
```

```
describe(df) # descriptive statistics
```

```
9×7 DataFrame

                                     0  Union{
                                     0  Union{
                                     0  Union{
                                     0  Union{
                                     0  Union{
                                     1 column omitted
```

3.2 Interpretation

Examining descriptive statistics is an important first step in any analysis. It is important to examine your descriptive statistics before skipping ahead to more sophisticated analyses, such as multilevel models.

In examining the descriptive statistics for this data, we get a sense of the data.

- `outcome` has a mean of approximately 52 and ranges from approximately 30 to 75.
- `warmth` and `physical punishment` are both variables that represent the number of times that parents use each of these forms of discipline in a week. The average of the former is about 3.5, while the average of the latter is about 2.5.
- `HDI`, the Human Development Index has an average of about 65, and a wide range.
- `identity` is a categorical variable for a hypothetical identity group, and has values of 0 and 1.
- `intervention` is also a categorical variable, and has values of 0 and 1.

4 Unconditional Models

4.1 Two Level Model

An *unconditional* multilevel model is a model with no independent variables. One should always run an unconditional model as the first step of a multilevel model in order to get a sense of the way that variation is apportioned in the model across the different levels.

4.1.1 The Equation

$$\text{outcome}_{ij} = \beta_0 + u_{0j} + e_{ij} \quad (4.1)$$

The Intraclass Correlation Coefficient (ICC) is given by:

$$\text{ICC} = \frac{\text{var}(u_{0j})}{\text{var}(u_{0j}) + \text{var}(e_{ij})} \quad (4.2)$$

In a two level multilevel model, the ICC provides a measure of the proportion of variation attributable to Level 2.

4.1.2 Run Models

4.1.2.1 Stata

```
use simulated_multilevel_data.dta // use data

mixed outcome || country: // unconditional model

estat icc // ICC
```

4.1.3 Interpretation

In each case, the software finds that nearly 8% of the variation in the outcome is explainable by the clustering of the observations in each country.

4.2 Three Level Model

4.2.1 The Equation

$$\text{outcome}_{ij} = \beta_0 + u_{0j} + v_{0i} + e_{ij} \quad (4.3)$$

As discussed in the main text, in a three level model, there are two intraclass correlation coefficients (StataCorp, 2023). The formulas for the Intraclass Correlation Coefficient (ICC) are given by (StataCorp, 2023):

$$\text{ICC} = \frac{\text{var}(u_{0j})}{\text{var}(u_{0j}) + \text{var}(v_{0i}) + \text{var}(e_{ij})} \quad (4.4)$$

Following StataCorp (2023), Equation 4.4 is the correlation of responses for person-timepoints from the same country but different persons.

$$\text{ICC} = \frac{\text{var}(u_{0j}) + \text{var}(v_{0i})}{\text{var}(u_{0j}) + \text{var}(v_{0i}) + \text{var}(e_{ij})} \quad (4.5)$$

Again, closely following StataCorp (2023), Equation 4.5 is the correlation of responses for person-timepoints from the same country and same person.

4.2.2 Run Models

4.2.2.1 Stata

```
use simulated_multilevel_longitudinal_data.dta // use data

mixed outcome || country: || id: // unconditional model

estat icc // ICC

0.34628041519632824

4.2.3 Interpretation

Each software suggests that almost 8% of the variation in the outcome is within time points for different individuals within the same country, while almost 35% of the variation in the outcome is within time points for the same individual within the same country.

5 Cross Sectional Multilevel Models

5.1 The Equation

Recall the general model of Equation 1.1, and the syntax outlined in Section 1.3. Below in Equation 5.1, we consider a more substantive example.

$$\begin{aligned} \text{outcome}_{ij} = & \beta_0 + \beta_1 \text{warmth}_{ij} + \\ & \beta_2 \text{physical punishment}_{ij} + \\ & \beta_3 \text{identity}_{ij} + \beta_4 \text{intervention}_{ij} + \beta_5 \text{HDI}_j + \\ & u_{0j} + u_{1j} \times \text{warmth}_{ij} + e_{ij} \end{aligned} \tag{5.1}$$

5.2 Correlated and Uncorrelated Random Effects

Consider the covariance matrix of random effects (e.g. u_{0j} and u_{1j}). In Equation 5.2 the covariances of the random effects are constrained to be zero.

$$\begin{bmatrix} \text{var}(u_{0j}) & 0 \\ 0 & \text{var}(u_{1j}) \end{bmatrix} \tag{5.2}$$

As discussed in the Chapter on multilevel models with cross-sectional data, however, one can consider a multilevel model in which the random effects are correlated, as is the case in Equation 5.3.

$$\begin{bmatrix} \text{var}(u_{0j}) & \text{cov}(u_{0j}, u_{1j}) \\ \text{cov}(u_{0j}, u_{1j}) & \text{var}(u_{1j}) \end{bmatrix} \tag{5.3}$$

Procedures for estimating models with uncorrelated and correlated random effects are detailed below (Bates et al., 2015; Bates, 2024; StataCorp, 2023).

Table 5.1: Correlated and Uncorrelated Random Effects

Software	Uncorrelated Random Effects	Correlated Random Effects
Stata	default	add option: <code>, cov(uns)</code>
R	separate random effects from grouping variable with <code> </code>	separate random effects from grouping variable with <code> </code>
Julia	separate terms for each random effect e.g. <code>(1 group) + (0 + x group)</code>	separate random effects from grouping variable with <code> </code> .

All models in the examples below are run with *uncorrelated* random effects, but could just as easily be run with *correlated* random effects.

5.3 Run Models

Continuous and Categorical Variables

Statistically—as noted in the main text—it is important to be clear on whether independent variables in one’s model are continuous or categorical. *Continuous* variables can be entered straightforwardly into statistical syntax. *Categorical* variables, on the other hand usually require specific attention in statistical software. In Stata, categorical variables are indicated in a statistical model by prefixing them with an `i.`. In R, categorical variables are distinguished by making them into factors e.g. `x <- factor(x)`. In Julia, categorical variables are created by using the `@transform` syntax detailed below.

5.3.1 Stata

5.3.1.1 Get The Data

```
use simulated_multilevel_data.dta
```

5.3.1.2 Run The Model

```
mixed outcome warmth physical_punishment i.identity i.intervention HDI || ///
country: warmth
```

5.3.2 R

5.3.2.1 Get The Data

```
library(haven)

df <- read_dta("simulated_multilevel_data.dta")
```

5.3.2.2 Change Some Variables To Categorical

```
df$identity <- factor(df$identity)

df$intervention <- factor(df$intervention)
```

5.3.2.3 Run The Model

Caution

`lme4` does not directly provide p values in results, because of some disagreement over exactly how these p values should be calculated. Therefore, in this Appendix, I also call `library(lmerTest)` to provide p values for `lme4` results.

Tip

R prefers to use scientific notation when possible. I find that the use of scientific notation can be confusing in reading results. I turn off scientific notation by setting a penalty for its use: `options(scipen = 999)`.

```
library(lme4)

library(lmerTest)
```

```
options(scipen = 999)

fit1 <- lmer(outcome ~ warmth + physical_punishment +
             identity + intervention + HDI +
             (1 + warmth || country),
             data = df)

summary(fit1)

physical_punishment	-0.991665	0.0797906	-12.43	<1e-34
identity: 1.0	-0.300475	0.217029	-1.38	0.1662
intervention: 1.0	0.639641	0.217452	2.94	0.0033
HDI	-0.0032286	0.0199255	-0.16	0.8713

5.4 Interpretation

Models suggest that parental warmth is associated with increases in the beneficial outcome, while physical punishment is associated with decreases in the beneficial outcome. The intervention is associated with increases in the outcome. There is insufficient evidence that either identity group or the Human Development Index are associated with the outcome.

6 Longitudinal Multilevel Models

6.1 The Data

The data employed in these examples are a longitudinal extension of the data described in Section 1.2.

6.2 The Equation

$$\text{outcome}_{itj} = \beta_0 + \beta_1 \text{parental warmth}_{itj} + \beta_2 \text{physical punishment}_{itj} + \beta_3 \text{time}_{itj} + \quad (6.1)$$

$$\beta_4 \text{identity}_{itj} + \beta_5 \text{intervention}_{itj} + \beta_6 \text{HDI}_j +$$

$$u_{0j} + u_{1j} \times \text{parental warmth}_{itj} +$$

$$v_{0ij} + v_{1ij} \times \text{time}_{itj} + e_{itj}$$

6.3 Growth Trajectories

Remember, following the discussion in the main text, that in longitudinal multilevel models, the variable for *time* assumes an important role as we are often thinking of a *growth trajectory* over time.

As discussed in the main text, think about a model where *identity* is a (1/0) variable for membership in one of two groups:

$$\text{outcome} = \beta_0 + \beta_t \text{time} + \beta_{\text{identity}} \text{identity} + \beta_{\text{interaction}} \text{identity} \times \text{time} + u_{0i} + e_{it}$$

Then, each identity group has its own intercept and time trajectory:

Table 6.1: Slope and Intercept for Each Group

Group	Intercept	Slope (Time Trajectory)
0	β_0	β_t
1	$\beta_0 + \beta_{\text{identity}}$	$\beta_t + \beta_{\text{interaction}}$

💡 Main Effects and Interactions

Thus, again following the main text, in longitudinal multilevel models, *main effects* modify the *intercept* of the time trajectory, while *interactions with time*, modify the *slope* of the time trajectory. Below, we run models with *main effects only*, then models with *main effects, and interactions with time*.

6.4 Run Models

⚠ Warning

Remember that we are estimating a model in which time points are nested inside families, who are in turn nested inside countries. For each software package, it is accordingly important to specify the way in which different levels of the data are nested. Pay careful attention to the syntax examples below with regard to `id` and `country`

6.4.1 Stata

LR test vs. linear model: $\chi^2(4) = 1247.84$ Prob > $\chi^2 = 0.0000$

Note: LR test is conservative and provided only for reference.

6.4.2 R

6.4.2.1 Get The Data

```
library(haven)

dfL <- read_dta("simulated_multilevel_longitudinal_data.dta")
```

6.4.2.2 Change Some Variables To Categorical

```
dfL$identity <- factor(dfL$identity)

dfL$intervention <- factor(dfL$intervention)
```

6.4.2.3 Run The Models

Caution

`lme4` does not directly provide p values in results, because of some disagreement over exactly how these p values should be calculated. Therefore, in this Appendix, I also call library `lmerTest` to provide p values for `lme4` results.

Tip

R prefers to use scientific notation when possible. I find that the use of scientific notation can be confusing in reading results. I turn off scientific notation by setting a penalty for its use: `options(scipen = 999)`.

6.4.2.3.1 Main Effects Only

```
library(lme4)

library(lmerTest)

options(scipen = 999)

fit2A <- lmer(outcome ~ t + warmth + physical_punishment +
```

```

        identity + intervention + HDI +
        (1 | country/id),
        data = dfL)

summary(fit2A)

```

6.5 Interpretation

The *main effects only model* suggests that time is associated with increases in the outcome. In the main effects model, main effects other than time, indicate whether a particular variable is associated with higher or lower intercepts of the time trajectory, at the beginning of the study time. Warmth is again associated with increases in the outcome, while physical punishment is associated with decreases in the outcome. Identity is again not associated with the outcome, while the intervention is associated with higher levels of the outcome. The Human Development Index is again not associated with the outcome.

The second model adds interactions with time to the first model. Results are largely similar to the prior model. However, here we not only examine whether main effects other than time

are associated with higher or lower time trajectories, but also whether particular variables are associated with differences in the slope of the time trajectory. In this case, we find insufficient evidence that any independent variable is associated with changes in the slope of the time trajectory.

Which Interactions To Test?

In this example—for the sake of illustration—I test the interaction of *every* independent variable with time. In many cases, it may make sense to test only one or two interactions of time with particular variables of key interest. Also, after finding, as I did in this model, that none of the interactions of other independent variables with time are significant, I might report the model with interactions, or might report only the results of the model with only main effects.

It may be illustrative to imagine how we would interpret the results had a particular interaction term been statistically significant. Let us consider one of the interaction terms with the largest coefficient, **intervention#time**. The interaction of the intervention with time is positive. Had this coefficient been statistically significant, it would have indicated that the intervention was associated with more rapid increases in the outcome over time *in addition to* the fact that the intervention is associated with higher initial levels of the outcome.

7 Reshaping Data

7.1 Introduction

Cross-sectional analyses (Chapter 5) make use of data in *wide* format: every row is a person, or family, and every person, or family, has a single row of data.

Longitudinal analyses (Chapter 6) make use of *long* data: every row is a person-timepoint, or family-timepoint, and every person, or family, has multiple rows of data.

Data therefore sometimes need to be *reshaped*, most often from *wide* format to *long* format. Almost any software that is capable of estimating multilevel models is capable of reshaping data.

Below, I detail the procedure for reshaping data in Stata and R.

7.2 Data in Wide Format

Note

The data below are in *wide* format.

Every individual in the data set has a *single row of data*. Every row in the data set is an *individual* or *family*.

Table 7.1: Data in Wide Format

Table 7.1: Table continues below

id	physical_punishment1	warmth1	outcome1	physical_punishment2
1.1	3	3	57.47	3
1.10	2	0	62.9	3
1.100	2	5	62.71	1
1.11	4	4	55.61	2
1.12	5	4	41.15	5
1.13	4	5	63.66	3

Table 7.2: Data in Wide Format

Table 7.2: Table continues below

warmth2	outcome2	physical_punishment3	warmth3	outcome3	country	HDI
4	55.06	1	2	58.77	1	69
0	56.67	2	0	68.22	1	69
4	51.58	2	5	55.51	1	69
5	50.9	3	3	48.02	1	69
5	45.4	3	4	55.86	1	69
3	64.81	3	3	58.3	1	69

Table 7.3: Data in Wide Format

family	identity	intervention
1	1	0
10	1	0
100	1	1
11	1	1
12	0	0
13	0	1

7.3 Data Management

Because reshaping your data dramatically changes the structure of your data...

1. It is a good idea to have your raw data saved in a location where it will not be changed, and can be retrieved again if the reshape command does not work correctly, or if you simply want to modify your reshaping data workflow. (CF Section 2.3)
2. Usually we want to work with only a *subset* of your data, to keep only the data in which we are interested.
 - In Stata, the command to keep only variables of interest would be: `keep y x z t`.
 - In R, one option would be to use the subset function: `mysubset <- subset(mydata, select = c(y, x, z, t))`

7.4 Reshaping Data From Wide To Long

Usually, we are most interested in reshaping data from *wide* to *long*.

7.4.1 Stata

In Stata, I only list variables that vary over time, or are *time varying*. Stata assumes that variables that are *not listed* do *not vary over time*, or are *time invariant*.

Notice also that our *time varying* data are in the *stub-time* format, e.g. `warmth1`, `warmth2`, `physical_punishment1` `physical_punishment2`, etc. Because the variables are named in this way, Stata knows to use the *stub* (e.g. `warmth`) as the variable name, and the numeric value, (e.g. 1, 2, 3) as the timepoint.

The `id` variable, whatever it is named, has to uniquely identify the observations. A useful Stata command here is `isid`, e.g. `isid id`. If your `id` variable is not unique, it is often due to missing values. `drop if id == .` usually solves the problem (assuming that your `id` variable is indeed named `id`, and not something else).

```
use simulated_multilevel_longitudinal_data_WIDE.dta, clear

describe

reshape long outcome physical_punishment warmth, i(id) j(wave)
```

Contains data from `simulated_multilevel_longitudinal_data_WIDE.dta`

Observations: 3,000
Variables: 15 3 Jul 2024 14:29

Variable name	Storage type	Display format	Value label	Variable label
id	str7	%9s		unique country family id
physical_puni~1	float	%9.0g		1 physical_punishment
warmth1	float	%9.0g		1 warmth
outcome1	float	%9.0g		1 outcome
physical_puni~2	float	%9.0g		2 physical_punishment
warmth2	float	%9.0g		2 warmth
outcome2	float	%9.0g		2 outcome
physical_puni~3	float	%9.0g		3 physical_punishment
warmth3	float	%9.0g		3 warmth
outcome3	float	%9.0g		3 outcome
country	float	%9.0g		country id
HDI	float	%9.0g		Human Development Index
family	float	%9.0g		family id
identity	float	%9.0g		hypothetical identity group variable

intervention	float	%9.0g	recieved intervention
--------------	-------	-------	-----------------------

Sorted by: id

(j = 1 2 3)

Data	Wide	->	Long
Number of observations	3,000	->	9,000
Number of variables	15	->	10
j variable (3 values)		->	wave
xij variables:			
	outcome1 outcome2 outcome3	->	outcome
physical_punishment1	physical_punishment2	physical_punishment3	->physical_punishment
	warmth1 warmth2 warmth3	->	warmth

7.4.2 R

In R, I only list variables that vary over time, or are *time varying*.

Notice also that our *time varying* data are in the *stub-time* format, e.g. `warmth1`, `warmth2`, `physical_punishment1` `physical_punishment2`, etc. In order to facilitate reshaping the data, it is helpful in R to insert an underscore (`_`) to separate the *stub* from the *time* variable.

```
library(dplyr) # data wrangling
```

```
library(tidyr) # tidy (reshape data)
```

```
# rename variables with "_" separator
```

```
df <- simulated_multilevel_longitudinal_data_WIDE %>%
  rename(outcome_1 = outcome1,
         outcome_2 = outcome2,
         outcome_3 = outcome3,
         physical_punishment_1 = physical_punishment1,
         physical_punishment_2 = physical_punishment2,
         physical_punishment_3 = physical_punishment3,
         warmth_1 = warmth1,
         warmth_2 = warmth2,
         warmth_3 = warmth3)
```

```
# pivot_longer() to long data

dfL <- df %>%
  pivot_longer(cols = c(outcome_1,
                        outcome_2,
                        outcome_3,
                        physical_punishment_1,
                        physical_punishment_2,
                        physical_punishment_3,
                        warmth_1,
                        warmth_2,
                        warmth_3),
              names_pattern = "(.+)_(.+)",
              names_to = c(".value", "t"))
```

7.5 Data in Long Format

i Note

The data below are in *long* format.

Every individual/family in the data set has a *multiple rows of data*. Every row in the data set is an *individual-timepoint* or *family-timepoint*.

Table 7.4: Data in Long Format

Table 7.4: Table continues below

country	HDI	family	id	identity	intervention	t
