# 1 Multilevel Multilingual

> “This curious world which we inhabit is more wonderful than it is convenient…” (Thoreau, 1975)

> “Mathematics is my secret. My secret weakness. I feel like a stubborn, helpless fool in the middle of a problem. Trapped and crazed. Also, thrilled.” (Schanen, 2021)

## 1.1 Introduction

Below, I describe the use of Stata (StataCorp, 2023), R (Bates et al., 2015; R Core Team, 2023), and Julia (Bates, 2024; Bezanson et al., 2017) to estimate multilevel models.

All of these software packages can estimate multilevel models and can visualize relationships in the data. However, there are substantial differences between the different packages: Stata is proprietary *for cost* software, which is very well documented and very intuitive. While it costs money to purchase Stata, the price is often very reasonable for academic and educational use. R is *free* open source software which is less intuitive, but there are many excellent resources for learning R. There is often a cost associated with purchasing books and other materials for learning R, which sometimes feels like it offsets the fact that R is free. Julia is newer open source software, also *free*, and ostensibly much faster than either Stata or R, which may be an important advantage when running multilevel models with very large data sets. At this point in time, both Stata and R feel much more *stable* than Julia which is still evolving software.

While any of these software packages can be used for learning and estimating multilevel models, I will offer my own opinion–based upon 15 years of teaching multilevel models at the doctoral level–that Stata offers the quickest pathway for learning the basic and advanced uses of multilevel models. I also believe the intuitive nature of Stata syntax contributes to accurate and replicable work in this area.

Table 1.1: Software for Multilevel Modeling

| Software | Cost | Ease of Use |
|---|---|---|
| Stata | some cost | learning curve, but very intuitive for both multilevel modeling and graphing. |

| Software | Cost | Ease of Use |
|---|---|---|
| R | free | learning curve: intuitive for multilevel modeling; but steeper learning curve for graphing (`ggplot`). |
| Julia | free | steep learning curve in general: steep learning curve for multilevel modeling; and very steep learning curve for graphing. Graphics libraries are very much under development and in flux. |

**Results Will Vary Somewhat**

Estimating multilevel models is a complex endeavor. The software details of how this is accomplished are beyond the purview of this book. Suffice it to say that across different software packages there will be differences in estimation routines, resulting in some numerical differences in the results provided by different software packages. Substantively speaking, however, results should agree across software.

**Multi-Line Commands**

Sometimes I have written commands out over multiple lines. I have done this for especially long commands, but have also sometimes done this simply for the sake of clarity. The different software packages have different approaches to multi-line commands.

1. By default, *Stata* ends a command at the end of a line. If you are going to write a multi-line command you should use the `///` line continuation characters.
2. *R* is the software that most naturally can be written using multiple lines, as R commands are usually clearly encased in parentheses (`()`) or continued with `+` signs.
3. Like *Stata*, *Julia* expects commands to end at the end of a line. If you are going to write a mult-line command, all commands except for the last line should end in a character that clearly indicates continuation, like a `+` sign. An alternative is to encase the entire Julia command in an outer set of parentheses (`()`).

**Running Statistical Packages in Quarto**

I used Quarto (Allaire et al., 2024) (https://quarto.org/) to create this Appendix. Quarto is a programming and publishing environment that can run multiple programming languages, including Stata, R and Julia, and that can write to multiple output formats including HTML, PDF, and MS Word. To run Stata, I used the `Statamarkdown` library (Hemken, 2023) in R to connect Stata to Quarto. Quarto has a built in connection to R,

and runs R without issue. To run Julia, I used the `JuliaCall` library (Li, 2019) in R to connect Quarto to Julia.
Of course, each of these programs can be run by itself, if you have them installed on your computer.

## 1.2 The Data

Datasets

The examples use the `simulated_multilevel_data.dta` and `simulated_multilevel_longitudinal_data.dta` files.
Here is a direct link to download the cross-sectional data.
Here is a direct link to download the longitudinal data.

Table 1.2: Sample of Simulated Multilevel Data

Table 1.2: Table continues below

| country | HDI | family | id | identity | intervention | physical_punishment |
|---|---|---|---|---|---|---|
| 1 | 69 | 1 | 1.1 | 1 | 0 | 3 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 2 |
| 1 | 69 | 3 | 1.3 | 0 | 1 | 3 |
| 1 | 69 | 4 | 1.4 | 1 | 0 | 0 |
| 1 | 69 | 5 | 1.5 | 1 | 0 | 4 |
| 1 | 69 | 6 | 1.6 | 0 | 1 | 5 |

Table 1.3: Sample of Simulated Multilevel Data

| warmth | outcome |
|---|---|
| 3 | 57.47 |
| 1 | 50.1 |
| 2 | 52.92 |
| 5 | 60.17 |
| 4 | 55.05 |
| 3 | 49.81 |

## 1.3 An Introduction To Equations and Syntax

To explain statistical syntax for each software, I consider the general case of a multilevel model with dependent variable `y`, independent variables `x` and `z`, clustering variable `group`, and a random slope for `x`. $i$ is the index for the person, while $j$ is the index for the group.

$$y = \beta_0 + \beta_1 x_{ij} + \beta_2 z_{ij} + u_{0j} + u_{1j} \times x_{ij} + e_{ij} \tag{1.1}$$

### 1.3.1 Stata

In Stata `mixed`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
mixed y x z || group: x
```

### 1.3.2 R

In R `lme4`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
library(lme4)

lmer(y ~ x + z + (1 + x || group), data = ...)
```

### 1.3.3 Julia

In Julia `MixedModels`, the syntax for a multilevel model of the form described in Equation 1.1 is:

```
using MixedModels

fit(MixedModel, @formula(y ~ x + z + (1 + x | group)), data)
```

# 2 Statistical Workflows

## 2.1 Statistical Software Is Best Run Using a Script

Many statistical workflows–whatever the statistical package being used–follow the same conceptual pattern.

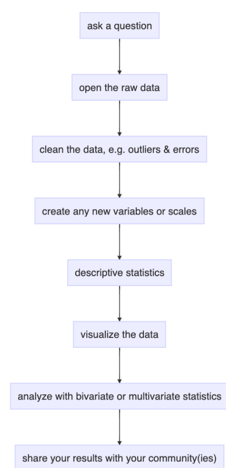

Figure 2.1: A Common Statistical Workflow

Increasingly, we want to think about workflows that are

- **documentable**, **transparent**, and **auditable**: We have a record of what we did if we want to double check our work, clarify a result, or develop a new project with a similar process. We, or others, can find the inevitable errors in our work, **and correct them**.
- **replicable**: Others can replicate our findings with the same or new data.
- **scalable**: We are developing a process that can be as easily used with *thousands* or *millions* of rows of data as it can with *ten* rows of data. We are developing a process that can be easily repeated if we are *constantly getting new or updated data*, e.g. getting new data every week, or every month.

## 2.2 Scripts

For most statistical workflows, we will often want to write a script or code. Data analysis scripts can be stored in a Quarto document (Allaire et al., 2024) as they are in this Appendix. Alternatively, every statistical package has its own unique format for storing scripts as a text file: in Stata, scripts are stored in `.do` files; in R, scripts are stored in `.R` files, and in Julia, scripts are stored in `.jl` files.

## 2.3 Script Flow

A good practice when writing a script, is to have a script that begins with the raw data, moves through any necessary re-coding or cleaning of the data, generates descriptive statistics, generates the appropriate multivariate results, and then generates any necessary visualizations.

## 2.4 Good Statistical Workflows Allow Multiple Statistical Packages

While this Appendix focuses on the use of each individual statistical package on its own, it is certainly possible to use multiple statistical packages as part of the same workflow. For example, one might employ Stata to carry out data management tasks, and then possibly use R to run a multilevel model with a more complicated multilevel structure, such as a cross-classified model, or Julia to more quickly run a model with a large data.

## 2.5 Good Statistical Workflows Require Safe Workspaces

It is also *very important* to be aware that good complex workflows are *highly iterative* and *highly collaborative*. Good complex workflows require a *safe workspace* in which team members feel free to admit their own errors, and help with others' mistakes in a non-judgmental fashion. Such a *safe environment* is necessary to build an environment where the *overall error rate* is low.

## 2.6 Good Statistical Workflows Require Patience And Can Be Psychologically Demanding

Developing a good documented and auditable workflow that is implemented in code requires a lot of patience, and often, **many iterations**. Working through these many iterations can be psychologically demanding. It is important to remember that careful attention to getting the details right early in the research process, while sometimes tiring and frustrating, will pay large dividends later on when the research is reviewed, presented, published and read.

## 2.7 Good Statistical Workflows Often Allow Multiple Principled Ways Forward

One of my most recent ideas about statistical workflows is that there are certainly *wrong* decisions that one can make with data.

For example, I would not want to write the paper that says that smoking prevents lung cancer, nor would I want to write a paper saying physical punishment is good for children.

That being said, I think there are often *multiple principled ways forward*.

Often the key is not so much to make the 100% correct decision, but to make one of *several possible principled decisions*.

Then after making a *principled decision*, one is *transparent* and *thorough* about describing the decision that one made.

For example, in implementing a multilevel analysis, I would have many choices: I could estimate only a random intercept; estimate one or more random slopes; or estimate all possible random slopes. The random effects could be correlated or uncorrelated. I could estimate only main effects, or could estimate interactions of several variables. Each of these would be a different, yet principled, approach to analyzing the data.

In science and statistics, we often want an answer that provides one clear direction. Instead, I'm increasingly convinced that the best science (and teaching!) often involves engaging in open discussion about the multiple possible alternatives, and then choosing one principled solution, and being transparent about its implementation.

# 3 Storing Statistical Data

## 3.1 Spreadsheets

Spreadsheets are sometimes used to collect and store data. Spreadsheets may sometimes be used because they are the only program that some individuals or agencies have for storing data. Spreadsheet programs may also be used because spreadsheets can be very intuitive and easy ways of managing small amounts of data.

However, spreadsheets may be problematic as an ultimate data storage solution for a number of reasons detailed below, especially as data sets grow in size. Notably, statistical programs like Stata, R, or Julia can all store additional information with each variable such as: a *variable label*, describing the contents of the variable, or the survey question that resulted in the variable; and a *value label*, which attaches qualitative information to each possible value of the response.

Spreadsheets do not generally contain this extra information about each variable, or column of data, which may lead to errors in working with quantitative information.

⚠ If Data Are Stored In A Spreadsheet, Variable Names Should Be Limited To a Single Row of the Spreadsheet

If spreadsheets are used to store data, the first row of the data should be used to list the variable names, as is seen in the example below. Rows other than the first row should not contain additional information about the variables, but should only contain data.

Table 3.1: Example Data As Stored in A Spreadsheet

Table 3.1: Table continues below

| country | HDI | family | id | identity | intervention | physical_punishment |
|---|---|---|---|---|---|---|
| 1 | 69 | 1 | 1.1 | 1 | 0 | 3 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 2 |
| 1 | 69 | 3 | 1.3 | 0 | 1 | 3 |
| 1 | 69 | 4 | 1.4 | 1 | 0 | 0 |
| 1 | 69 | 5 | 1.5 | 1 | 0 | 4 |
| 1 | 69 | 6 | 1.6 | 0 | 1 | 5 |

Table 3.2: Example Data As Stored in A Spreadsheet

| warmth | outcome |
|---|---|
| 3 | 57.47 |
| 1 | 50.1 |
| 2 | 52.92 |
| 5 | 60.17 |
| 4 | 55.05 |
| 3 | 49.81 |

## 3.2 Data in Statistical Format

I load the data from a statistical program.

### 3.2.1 Describe The Data

Notice how a description of the data contains information that helps us to understand the variables.

Table 3.3: Variable Labels

| pos | variable | label |
|---|---|---|
| 1 | country | country id |
| 2 | HDI | Human Development Index |
| 3 | family | family id |
| 4 | id | unique country family id |
| 5 | identity | hypothetical identity group variable |
| 6 | intervention | recieved intervention |
| 7 | physical_punishment | physical punishment in past week |
| 8 | warmth | parental warmth in past week |
| 9 | outcome | beneficial outcome |

### 3.2.2 Descriptive Statistics

Variable Labels and Value Labels Help Us Understand Our Data

Notice how the descriptive statistics and graph are informative in that they contain information on the *variable label* and *value label*. These help us to get an intuitive sense of the information in the data. We see this information when we list out the data as well.

Table 3.4: Descriptive Statistics

Table 3.4: Table continues below

| country | HDI | family | id |
|---|---|---|---|
| 1 : 100 | Min. :33.00 | Min. : 1.00 | Length:3000 |
| 2 : 100 | 1st Qu.:53.00 | 1st Qu.: 25.75 | Class :character |
| 3 : 100 | Median :70.00 | Median : 50.50 | Mode :character |
| 4 : 100 | Mean :64.77 | Mean : 50.50 | NA |
| 5 : 100 | 3rd Qu.:81.00 | 3rd Qu.: 75.25 | NA |

| Median :52.45 |
| Mean :52.43 |
| 3rd Qu.:56.86 |
| Max. :74.84 |
| NA |

### 3.2.3 Graph

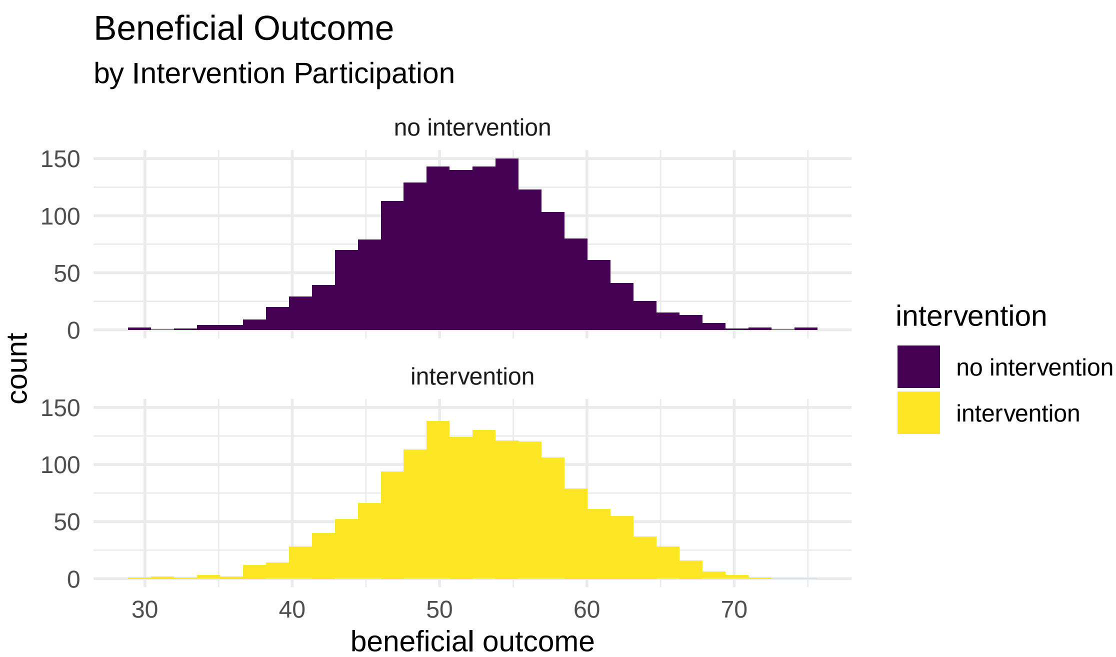

Figure 3.1: Graph from Data Stored in Statistical Software

### 3.2.4 List Out A Sample Of The Data

Table 3.7: Sample of Data

Table 3.7: Table continues below

| country | HDI | family | id | identity | intervention |
|---|---|---|---|---|---|
| 1 | 69 | 1 | 1.1 | Identity A | no intervention |
| 1 | 69 | 2 | 1.2 | Identity A | intervention |
| 1 | 69 | 3 | 1.3 | Identity B | intervention |
| 1 | 69 | 4 | 1.4 | Identity A | no intervention |
| 1 | 69 | 5 | 1.5 | Identity A | no intervention |
| 1 | 69 | 6 | 1.6 | Identity B | intervention |

Table 3.8: Sample of Data

| physical_punishment | warmth | outcome |
|---|---|---|
| 3 | 3 | 57.47 |
| 2 | 1 | 50.1 |
| 3 | 2 | 52.92 |
| 0 | 5 | 60.17 |
| 4 | 4 | 55.05 |
| 5 | 3 | 49.81 |

## 3.3 Data In Spreadsheet Format

I now import the spreadsheet data file. I use the first row of data as variable names.

We see right away that the data are less informative.

### 3.3.1 Describe The Data

Notice how a description of the data no longer contains much of the information that helped us to understand the variables.

Table 3.9: Example Data As Stored in A Spreadsheet

| pos | variable | label |
|---|---|---|
| 1 | country | NA |
| 2 | HDI | NA |
| 3 | family | NA |

Table 3.9: Example Data As Stored in A Spreadsheet

| pos | variable | label |
|---|---|---|
| 4 | id | NA |
| 5 | identity | NA |
| 6 | intervention | NA |
| 7 | physical_punishment | NA |
| 8 | warmth | NA |
| 9 | outcome | NA |

Table 3.10: Example Data As Stored in A Spreadsheet

Table 3.10: Table continues below

| country | HDI | family | id | identity | intervention | physical_punishment |
|---|---|---|---|---|---|---|
| 1 | 69 | 1 | 1.1 | 1 | 0 | 3 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 2 |
| 1 | 69 | 3 | 1.3 | 0 | 1 | 3 |
| 1 | 69 | 4 | 1.4 | 1 | 0 | 0 |
| 1 | 69 | 5 | 1.5 | 1 | 0 | 4 |
| 1 | 69 | 6 | 1.6 | 0 | 1 | 5 |

Table 3.11: Example Data As Stored in A Spreadsheet

| warmth | outcome |
|---|---|
| 3 | 57.47 |
| 1 | 50.1 |
| 2 | 52.92 |
| 5 | 60.17 |
| 4 | 55.05 |
| 3 | 49.81 |

Warning

Adding this valuable information back into the data set may take a great deal of extra effort.

### 3.3.2 Descriptive Statistics

Notice here how the descriptive statistics and graph are much less informative. For example, it is now not immediately clear what the values of `identity` or `intervention` represent. The information on variable labels and value labels will have to be added back into the data when preparing a final product for dissemination.

Table 3.12: Descriptive Statistics

Table 3.12: Table continues below

| country | HDI | family | id |
|---|---|---|---|
| Min. : 1.0 | Min. :33.00 | Min. : 1.00 | Length:3000 |
| 1st Qu.: 8.0 | 1st Qu.:53.00 | 1st Qu.: 25.75 | Class :character |
| Median :15.5 | Median :70.00 | Median : 50.50 | Mode :character |
| Mean :15.5 | Mean :64.77 | Mean : 50.50 | NA |
| 3rd Qu.:23.0 | 3rd Qu.:81.00 | 3rd Qu.: 75.25 | NA |
| Max. :30.0 | Max. :87.00 | Max. :100.00 | NA |

Table 3.13: Descriptive Statistics

Table 3.13: Table continues below

| identity | intervention | physical_punishment | warmth |
|---|---|---|---|
| Min. :0.0000 | Min. :0.0000 | Min. :0.000 | Min. :0.000 |
| 1st Qu.:0.0000 | 1st Qu.:0.0000 | 1st Qu.:2.000 | 1st Qu.:2.000 |
| Median :0.0000 | Median :0.0000 | Median :2.000 | Median :4.000 |
| Mean :0.4977 | Mean :0.4843 | Mean :2.479 | Mean :3.522 |

Table 3.14: Descriptive Statistics

| outcome |
|---|
| Min. :29.61 |
| 1st Qu.:48.02 |
| Median :52.45 |
| Mean :52.43 |
| 3rd Qu.:56.86 |
| Max. :74.84 |

### 3.3.3 Graph

While the graph has an informative title, as well as informative axis labels, a crucial piece of information is missing: what each status of the intervention represents.

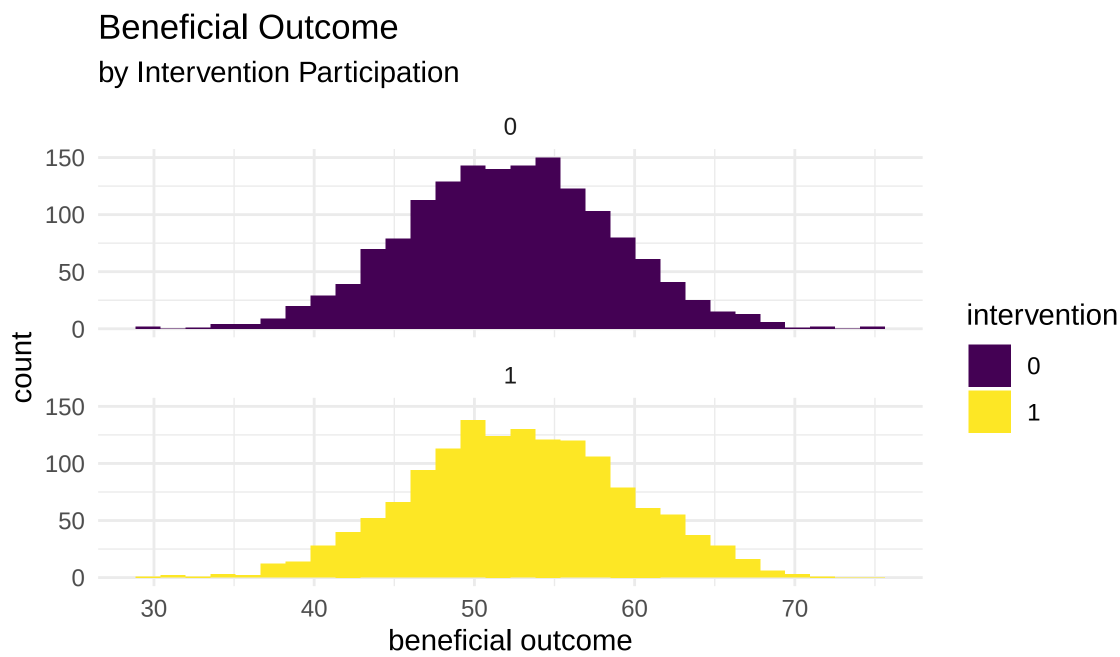

Figure 3.2: Graph from Data Stored in Spreadsheet

## 3.4 A Few Final Issues

Notice, finally, how spreadsheets don't enforce the idea of whether variables are *numeric*, or *text*, and so would allow storage of different types of information in the same column. Relatedly, *numeric* variables may be improperly stored as *text*, often necessitating recoding before graphical or statistical procedures can be employed.

Second, a spreadsheet would allow some of your columns to have the same name, which might make data difficult to work with in other software.

Lastly, spreadsheets do not enforce the idea that the data have a *structure* wherein the *column header* is a *variable name*, while the *other rows* are *data*.

Table 3.15: A Spreadsheet Table With Problematic Organization

| x | y | verylongvariablename | verylongvariablename |
|---|---|---|---|
| 100 | 1 | Smith | 20 |
| 200 | 2 | 30 | NA |
| not applicable | x | yes | 60 |
| | | some other random information | |

## 3.5 File Organization

Files for all of your work should not be stored all together in `downloads`. Ideally, you should have a specific set of folders for your work. Each project, should be stored in its own individual folder. Ideally, each project folder would have a separate sub-folder for separate aspects of the project such as data, code or syntax, and various outputs.

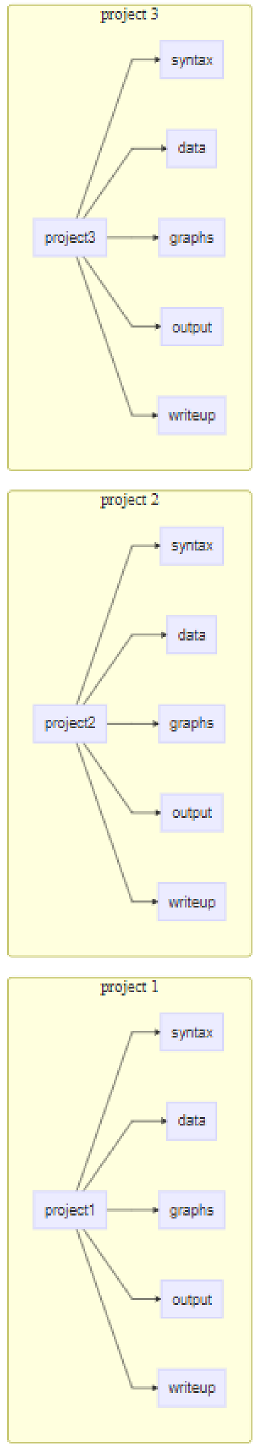

Figure 3.3: A Hypothetical Set of Folders and Subfolders

# 4 Descriptive Statistics

## 4.1 Descriptive Statistics

### 4.1.1 Stata

```
use simulated_multilevel_data.dta // use data
```

We use `summarize` for *continuous* variables, and `tabulate` for *categorical* variables.

```
summarize outcome warmth physical_punishment HDI

tabulate identity

tabulate intervention
```

```
    Variable |        Obs        Mean    Std. dev.       Min        Max

          1 |      1,453       48.43      100.00
------------+-----------------------------------
      Total |      3,000      100.00
```

### 4.1.2 R

```r
library(haven) # read data in Stata format

df <- read_dta("simulated_multilevel_data.dta")
```

R's descriptive statistics functions rely heavily on whether a variable is a *numeric* variable, or a *factor* variable. Below, I convert two variables to factors (`factor`) before using `summary`[1] to generate descriptive statistics.

```r
df$country <- factor(df$country)

df$identity <- factor(df$identity)

df$intervention <- factor(df$intervention)

summary(df)
```

```
    country         HDI            family              id               identity
 1      : 100   Min.   :33.00   Min.   :  1.00   Length:3000        0:1507
 2      : 100   1st Qu.:53.00   1st Qu.: 25.75   Class :character   1:1493
 3      : 100   Median :70.00   Median : 50.50   Mode  :character
 4      : 100   Mean   :64.77   Mean   : 50.50
 5      : 100   3rd Qu.:81.00   3rd Qu.: 75.25
 6      : 100   Max.   :87.00   Max.   :100.00
 (Other):2400
 intervention physical_punishment     warmth          outcome
 0:1547       Min.   :0.000       Min.   :0.000   Min.   :29.61
 1:1453       1st Qu.:2.000       1st Qu.:2.000   1st Qu.:48.02
```

[1] `skimr` is an excellent new alternative library for generating descriptive statistics in R.

```
      Median :2.000       Median :4.000   Median :52.45  
      Mean   :2.479       Mean   :3.522   Mean   :52.43  
      3rd Qu.:3.000       3rd Qu.:5.000   3rd Qu.:56.86  
      Max.   :5.000       Max.   :7.000   Max.   :74.84  
```

### 4.1.3 Julia

```julia
using Tables, MixedModels, MixedModelsExtras, StatFiles, DataFrames, CategoricalArrays, DataI

df = DataFrame(load("simulated_multilevel_data.dta"))
```

Similarly to R, Julia relies on the idea of *variable type*. I use `transform` to convert the appropriate variables to *categorical* variables.

```julia
@transform!(df, :country = categorical(:country))

@transform!(df, :identity = categorical(:identity))

@transform!(df, :intervention = categorical(:intervention))
```

## 4.2 Interpretation

Examining descriptive statistics is an important first step in any analysis. It is important to examine your descriptive statistics before skipping ahead to more sophisticated analyses, such as multilevel models.

In examining the descriptive statistics for this data, we get a sense of the data.

- `outcome` has a mean of approximately 52 and ranges from approximately 30 to 75.
- `warmth` and `physical punishment` are both variables that represent the number of times that parents use each of these forms of discipline in a week. The average of the former is about 3.5, while the average of the latter is about 2.5.
- `HDI`, the Human Development Index has an average of about 65, and a wide range.
- `identity` is a categorical variable for a hypothetical identity group, and has values of 0 and 1.
- `intervention` is also a categorical variable, and has values of 0 and 1.

# 5 Unconditional Models

## 5.1 Two Level Model

An *unconditional* multilevel model is a model with no independent variables. One should always run an unconditional model as the first step of a multilevel model in order to get a sense of the way that variation is apportioned in the model across the different levels.

### 5.1.1 The Equation

$$\text{outcome}_{ij} = \beta_0 + u_{0j} + e_{ij} \tag{5.1}$$

The Intraclass Correlation Coefficient (ICC) is given by:

$$\text{ICC} = \frac{var(u_{0j})}{var(u_{0j}) + var(e_{ij})} \tag{5.2}$$

In a two level multilevel model, the ICC provides a measure of the proportion of variation attributable to Level 2.

### 5.1.2 Run Models

### 5.1.3 Interpretation

In each case, the software finds that nearly 8% of the variation in the outcome is explainable by the clustering of the observations in each country.

## 5.2 Three Level Model

### 5.2.1 The Equation

$$\text{outcome}_{ij} = \beta_0 + u_{0j} + v_{0i} + e_{ij} \tag{5.3}$$

As discussed in the main text, in a three level model, there are two intraclass correlation coefficients (StataCorp, 2023). The formulas for the Intraclass Correlation Coefficient (ICC) are given by (StataCorp, 2023):

$$\text{ICC} = \frac{var(u_{0j})}{var(u_{0j}) + var(v_{0i}) + var(e_{ij})} \tag{5.4}$$

Following StataCorp (2023), Equation 5.4 is the correlation of responses for person-timepoints from the same country but different persons.

$$\text{ICC} = \frac{var(u_{0j}) + var(v_{0i})}{var(u_{0j}) + var(v_{0i}) + var(e_{ij})} \tag{5.5}$$

Again, closely following StataCorp (2023), Equation 5.5 is the correlation of responses for person-timepoints from the same country and same person.

### 5.2.2 Run Models

id        (Intercept)  11.72401 3.42403
country   (Intercept)   3.23190 1.79775
Residual               28.23426 5.31359
 Number of obs: 9000; levels of grouping factors: 3000, 30

  Fixed-effects parameters:

               Coef.  Std. Error       z  Pr(>|z|)

(Intercept)  53.3777    0.338785  157.56    <1e-99
```

```
3.23190 / (11.72401 + 3.23190 + 28.23426)
```

```
0.07482952718176382
```

```
(3.23190 + 11.72401) / (11.72401 + 3.23190 + 28.23426)
```

```
0.34628041519632824
```

### 5.2.3 Interpretation

Each software suggests that almost 8% of the variation in the outcome is within time points for different individuals within the same country, while almost 35% of the variation in the outcome is within time points for the same individual within the same country.

# 6 Cross Sectional Multilevel Models

## 6.1 The Equation

Recall the general model of Equation 1.1, and the syntax outlined in Section 1.3. Below in Equation 6.1, we consider a more substantive example.

$$\text{outcome}_{ij} = \beta_0 + \beta_1 \text{warmth}_{ij} + \tag{6.1}$$

$$\beta_2 \text{physical punishment}_{ij} +$$

$$\beta_3 \text{identity}_{ij} + \beta_4 \text{intervention}_{ij} + \beta_5 \text{HDI}_j +$$

$$u_{0j} + u_{1j} \times \text{warmth}_{ij} + e_{ij}$$

## 6.2 Correlated and Uncorrelated Random Effects

Consider the covariance matrix of random effects (e.g. $u_{0j}$ and $u_{1j}$). In Equation 6.2 the covariances of the random effects are constrained to be zero.

$$\begin{bmatrix} var(u_{0j}) & 0 \\ 0 & var(u_{1j}) \end{bmatrix} \tag{6.2}$$

As discussed in the Chapter on multilevel models with cross-sectional data, however, one can consider a multilevel model in which the random effects are correlated, as is the case in Equation 6.3.

$$\begin{bmatrix} var(u_{0j}) & cov(u_{0j}, u_{1j}) \\ cov(u_{0j}, u_{1j}) & var(u_{1j}) \end{bmatrix} \tag{6.3}$$

Procedures for estimating models with uncorrelated and correlated random effects are detailed below (Bates et al., 2015; Bates, 2024; StataCorp, 2023).

Table 6.1: Correlated and Uncorrelated Random Effects

| Software | Uncorrelated Random Effects | Correlated Random Effects |
|---|---|---|
| Stata | default | add option: `, cov(uns)` |
| R | separate random effects from grouping variable with `||` | separate random effects from grouping variable with `|` |
| Julia | separate terms for each random effect e.g. `(1 | group) + (0 + x | group)` | separate random effects from grouping variable with `|`. |

All models in the examples below are run with *uncorrelated* random effects, but could just as easily be run with *correlated* random effects.

## 6.3 Run The Models

> ⚠ Continuous and Categorical Variables
>
> Statistically–as noted in the main text–it is important to be clear on whether independent variables in one's model are continuous or categorical. *Continuous* variables can be entered straightforwardly into statistical syntax. *Categorical* variables, on the other hand usually require specific attention in statistical software. In Stata, categorical variables are indicated in a statistical model by prefixing them with an `i.`. In R, categorical variables are distinguished by making them into factors e.g. `x <- factor(x)`. In Julia, categorical variables are created by using the `@transform` syntax detailed below.

### 6.3.1 Stata

### 6.3.2 R

#### 6.3.2.1 Get The Data

```r
library(haven)

df <- read_dta("simulated_multilevel_data.dta")
```

#### 6.3.2.2 Change Some Variables To Categorical

```r
df$identity <- factor(df$identity)

df$intervention <- factor(df$intervention)
```

#### 6.3.2.3 Run The Model

> **Caution**
>
> `lme4` does not directly provide p values in results, because of some disagreement over exactly how these p values should be calculated. Therefore, in this Appendix, I also call library `lmerTest` to provide p values for `lme4` results.

> **Tip**
>
> R prefers to use scientific notation when possible. I find that the use of scientific notation can be confusing in reading results. I turn off scientific notation by setting a penalty for its use: `options(scipen = 999)`.

```r
library(lme4)

library(lmerTest)
```

```r
options(scipen = 999)

fit1 <- lmer(outcome ~ warmth + physical_punishment +
               identity + intervention + HDI +
               (1 + warmth || country),
             data = df)

summary(fit1)
```

```

## 6.4 Interpretation

Models suggest that parental warmth is associated with increases in the beneficial outcome, while physical punishment is associated with decreases in the beneficial outcome. The intervention is associated with increases in the outcome. There is insufficient evidence that either identity group or the Human Development Index are associated with the outcome.

# 7 Longitudinal Multilevel Models

## 7.1 The Data

The data employed in these examples are a longitudinal extension of the data described in Section 1.2.

## 7.2 The Equation

$$\text{outcome}_{itj} = \beta_0 + \beta_1 \text{parental warmth}_{itj} + \beta_2 \text{physical punishment}_{itj} + \beta_3 \text{time}_{itj} + \tag{7.1}$$

$$\beta_4 \text{identity}_{itj} + \beta_5 \text{intervention}_{itj} + \beta_6 \text{HDI}_j +$$

$$u_{0j} + u_{1j} \times \text{parental warmth}_{itj} +$$

$$v_{0ij} + v_{1ij} \times \text{time}_{itj} + e_{itj}$$

## 7.3 Growth Trajectories

Remember, following the discussion in the main text, that in longitudinal multilevel models, the variable for *time* assumes an important role as we are often thinking of a *growth trajectory* over time.

As discussed in the main text, think about a model where *identity* is a (1/0) variable for membership in one of two groups:

$$\text{outcome} = \beta_0 + \beta_t \text{time} + \beta_{\text{identity}} \text{identity} + \beta_{\text{interaction}} \text{identity} \times \text{time} + u_{0i} + e_{it}$$

Then, each identity group has its own intercept and time trajectory:

Table 7.1: Slope and Intercept for Each Group

| Group | Intercept | Slope (Time Trajectory) |
|---|---|---|
| 0 | $\beta_0$ | $\beta_t$ |
| 1 | $\beta_0 + \beta_{\text{identity}}$ | $\beta_t + \beta_{\text{interaction}}$ |

Main Effects and Interactions

Thus, again following the main text, in longitudinal multilevel models, *main effects* modify the *intercept* of the time trajectory, while *interactions with time*, modify the *slope* of the time trajectory. Below, we run models with *main effects only*, then models with *main effects, and interactions with time.*

## 7.4 Run The Models

Warning

Remember that we are estimating a model in which time points are nested inside families, who are in turn nested inside countries. For each software package, it is accordingly important to specify the way in which different levels of the data are nested. Pay careful attention to the syntax examples below with regard to `id` and `country`

### 7.4.1 Stata

#### 7.4.1.1 Get The Data

```

### 7.4.2 R

#### 7.4.2.1 Get The Data

```r
library(haven)

dfL <- read_dta("simulated_multilevel_longitudinal_data.dta")
```

#### 7.4.2.2 Change Some Variables To Categorical

```r
dfL$identity <- factor(dfL$identity)

dfL$intervention <- factor(dfL$intervention)
```

#### 7.4.2.3 Run The Models

> Caution
>
> `lme4` does not directly provide p values in results, because of some disagreement over exactly how these p values should be calculated. Therefore, in this Appendix, I also call library `lmerTest` to provide p values for `lme4` results.

> Tip
>
> R prefers to use scientific notation when possible. I find that the use of scientific notation can be confusing in reading results. I turn off scientific notation by setting a penalty for its use: `options(scipen = 999)`.

##### 7.4.2.3.1 Main Effects Only

```r
library(lme4)

library(lmerTest)

options(scipen = 999)

fit2A <- lmer(outcome ~ t + warmth + physical_punishment +
```

```r
                identity + intervention + HDI +

## 7.5 Interpretation

The *main effects only model* suggests that time is associated with increases in the outcome. In the main effects model, main effects other than time, indicate whether a particular variable is associated with higher or lower intercepts of the time trajectory, at the beginning of the study time. Warmth is again associated with increases in the outcome, while physical punishment is associated with decreases in the outcome. Identity is again not associated with the outcome, while the intervention is associated with higher levels of the outcome. The Human Development Index is again not associated with the outcome.

The second model adds interactions with time to the first model. Results are largely similar to the prior model. However, here we not only examine whether main effects other than time are associated with higher or lower time trajectories, but also whether particular variables are associated with differences in the slope of the time trajectory. In this case, we find insufficient evidence that any independent variable is associated with changes in the slope of the time trajectory.

**Which Interactions To Test?**

In this example–for the sake of illustration–I test the interaction of *every* independent variable with time. In many cases, it may make sense to test only only one or two interactions of time with particular variables of key interest. Also, after finding, as I did in this model, that none of the interactions of other independent variables with time are significant, I might report the model with interactions, or might report only the results of the model with only main effects.

It may be illustrative to imagine how we would interpret the results had a particular interaction term been statistically significant. Let us consider one of the interaction terms with the largest coefficient, `intervention#time`. The interaction of the intervention with time is positive. Had this coefficient been statistically signifcant, it would have indicated that the intervention was associated with more rapid increases in the outcome over time *in addition to* the fact that the intervention is associated with higher initial levels of the outcome.

# 8 Multilevel Logistic Regression

Below, I detail the procedure for multilevel logistic regression models in Stata and R.

## 8.1 The Data

The data employed in these examples are the cross-sectional data described in Section 1.2.

## 8.2 The Equation

To explain statistical syntax for Stata and R, I consider the general case of a multilevel model with *categorical* dependent variable `y`, independent variables `x` and `z`, clustering variable `group`, and a random slope for `x`. $i$ is the index for the person, while $j$ is the index for the group.

$$\ln \left( \frac{p(y)}{1 - p(y)} \right) = \beta_0 + \beta_1 x_{ij} + \beta_2 z_{ij} + u_{0j} \tag{8.1}$$

> Correlated and Uncorrelated Random Effects in Logistic Regression
>
> The reader is referred to the discussion of correlated and uncorrelated random effects in Section 6.2

### 8.2.1 Stata

In Stata `mixed`, the syntax for a multilevel model of the form described in Equation 8.1 is:

```
melogit y x z || group:
```

### 8.2.2 R

In R `lme4`, the syntax for a multilevel model of the form described in Equation 8.1 is:

```
library(lme4)

glmer(y ~ x + z + (1 | group), data = ...)
```

## 8.3 Run Models

Less Variation In Logistic Than Linear Models

Note that in *logistic* regression models, there is less variation to work with–due to the fact that the outcome is `1/0`, than there is in *linear* models. Therefore, in the models below, I do not attempt to estimate a random slope in addition to a random intercept, as I do in Section 6.

### 8.3.1 Stata

#### 8.3.1.1 Get The Data

```
use simulated_multilevel_data.dta

generate outcome_category = outcome > 52 // dichotomous outcome
```

#### 8.3.1.2 Run The Model

As suggested in Equation 8.1, odds ratios are obtained by exponentiating the $\beta$ coefficients: $e^{\beta}$. Stata provides the odds ratios automatically with option `, or`.

```
melogit outcome_category warmth physical_punishment i.identity i.intervention HDI || ///
country:, or
```

```
Fitting fixed-effects model:

### 8.3.2 R

#### 8.3.2.1 Get The Data

```
library(haven)

df <- read_dta("simulated_multilevel_data.dta")

df$outcome_category <- 0 # initialize to 0

df$outcome_category[df$outcome > 52] <- 1 # dichotomous outcome
```

#### 8.3.2.2 Change Some Variables To Categorical

```
df$identity <- factor(df$identity)

df$intervention <- factor(df$intervention)
```

#### 8.3.2.3 Run The Model

> Caution
>
> `lme4` does not directly provide p values in results, because of some disagreement over exactly how these p values should be calculated. Therefore, in this Appendix, I also call library `lmerTest` to provide p values for `lme4` results.

> Tip
>
> R prefers to use scientific notation when possible. I find that the use of scientific notation can be confusing in reading results. I turn off scientific notation by setting a penalty for its use: `options(scipen = 999)`.

```
library(lme4)

library(lmerTest)
```

```r
options(scipen = 999)

fit3 <- glmer(outcome_category ~ warmth + physical_punishment +
                identity + intervention + HDI +
                (1 | country),
              family = binomial(link = "logit"),
              data = df)

summary(fit3)
```

```
Generalized linear mixed model fit by maximum likelihood (Laplace
  Approximation) [glmerMod]

#### 8.3.2.4 Calculate Odds Ratios

R requires one to use a bit of extra syntax to extract the odds ratios. As suggested in Equation 8.1, odds ratios are obtained by exponentiating the $\beta$ coefficients: $e^{\beta}$.

```
exp(fixef(fit3))
```

```

      intervention1                 HDI
          1.1915893           0.9990492
```

# 9 # Models With Three or More Levels and Cross-Classified Models

## 9.1 Introduction

A two level multilevel model imagines that *Level 1* units are nested in *Level 2* units. A three level multilevel model imagines that *Level 1* units are nested in *Level 2* units, which are in turn nested in *Level 3*. As more levels are added to the model (e.g. *Level 4*), we imagine all of these levels to be hierarchically nested.

A *cross classified* model imagines that the nesting is not hierarchical, but rather that there are two sets of clusters or nestings in which individuals may be nested.

Below, I describe the use of Stata, R, and Julia to estimate these models.

## 9.2 Three Or More Levels

### 9.2.1 The Data

I use the *longitudinal* data from *Multilevel Thinking* (Section 1.2) to which I have added an extra level of *United Nations Region* (Arel-Bundock et al., 2018). This data thus requires a four level model.

### 9.2.2 The Equation

$$\text{outcome}_{itjk} = \beta_0 + \beta_1 \text{parental warmth}_{itjk} + \beta_2 \text{physical punishment}_{itjk} + \beta_3 \text{time}_{itjk} + \tag{9.1}$$

$$\beta_4 \text{identity}_{itjk} + \beta_5 \text{intervention}_{itjk} + \beta_6 \text{HDI}_{itjk} +$$

$$w_{0k} + u_{0j} + v_{0i} + e_{itjk}$$

Here we imagine $w_{0k}$ (region), $u_{0j}$ (country) and $v_{0i}$ (family) are hierarchically nested effects.

### 9.2.3 Run The Models

#### 9.2.3.1 Stata

##### 9.2.3.1.1 Get The Data

```
use "fourlevel.dta", clear
```

##### 9.2.3.1.2 Unconditional Model

### 9.2.4 Interpretation

There is group level variation attributable to individual, country, and region.

As in other models, parental warmth, and participation in the intervention are associated with increases in the outcome. Parental use of physical punishment is associated with decreases in the outcome.

## 9.3 Cross-Classified Models

### 9.3.1 The Data

I use the *cross-sectional* data from *Multilevel Thinking* (Section 1.2) to which I have added an extra level of a hypothetical language.

### 9.3.2 The Equation

$$\text{outcome}_{ijm} = \beta_0 + \beta_1 \text{parental warmth}_{ijm} + \beta_2 \text{physical punishment}_{ijm} + \beta_3 \text{time}_{ijm} + \quad (9.2)$$

$$\beta_4 \text{identity}_{ijm} + \beta_5 \text{intervention}_{ijm} + \beta_6 \text{HDI}_{ijm} +$$

$$u_{0j} + m_{0m} + e_{ijm}$$

Here $u_{0j}$ (country) and $m_{0m}$ (language) are not nested hierarchically, but are *cross classified*.

### 9.3.3 Run The Models

#### 9.3.3.1 Stata

##### 9.3.3.1.1 Get The Data

### 9.3.4 Interpretation

There is group level variation attributable to both language and country.

As in other models, parental warmth, and participation in the intervention are associated with increases in the outcome. Parental use of physical punishment is associated with decreases in the outcome.

# 10 Reshaping Data

## 10.1 Introduction

Cross-sectional analyses (Section 6) make use of data in *wide* format: every row is a person, or family, and every person, or family, has a single row of data.

Longitudinal analyses (Section 7) make use of *long* data: every row is a person-timepoint, or family-timepoint, and every person, or family, has multiple rows of data.

Data therefore sometimes need to be *reshaped*, most often from *wide* format to *long* format. Almost any software that is capable of estimating multilevel models is capable of reshaping data.

Below, I detail the procedure for reshaping data in Stata and R.

## 10.2 Data in Wide Format

> Note
>
> The data below are in *wide* format.
> Every individual in the data set has a *single row of data*. Every row in the data set is an *individual* or *family*.

Table 10.1: Data in Wide Format

Table 10.1: Table continues below

| id | physical_punishment1 | warmth1 | outcome1 | physical_punishment2 |
|---|---|---|---|---|
| 1.1 | 3 | 3 | 57.47 | 3 |
| 1.10 | 2 | 0 | 62.9 | 3 |
| 1.100 | 2 | 5 | 62.71 | 1 |
| 1.11 | 4 | 4 | 55.61 | 2 |
| 1.12 | 5 | 4 | 41.15 | 5 |
| 1.13 | 4 | 5 | 63.66 | 3 |

Table 10.2: Data in Wide Format

Table 10.2: Table continues below

| warmth2 | outcome2 | physical_punishment3 | warmth3 | outcome3 | country | HDI |
|---|---|---|---|---|---|---|
| 4 | 55.06 | 1 | 2 | 58.77 | 1 | 69 |
| 0 | 56.67 | 2 | 0 | 68.22 | 1 | 69 |
| 4 | 51.58 | 2 | 5 | 55.51 | 1 | 69 |
| 5 | 50.9 | 3 | 3 | 48.02 | 1 | 69 |
| 5 | 45.4 | 3 | 4 | 55.86 | 1 | 69 |
| 3 | 64.81 | 3 | 3 | 58.3 | 1 | 69 |

Table 10.3: Data in Wide Format

| family | identity | intervention |
|---|---|---|
| 1 | 1 | 0 |
| 10 | 1 | 0 |
| 100 | 1 | 1 |
| 11 | 1 | 1 |
| 12 | 0 | 0 |
| 13 | 0 | 1 |

## 10.3 Data Management

Because reshaping your data dramatically changes the structure of your data…

1. It is a good idea to have your raw data saved in a location where it will not be changed, and can be retrieved again if the reshape command does not work correctly, or if you simply want to modify your reshaping data workflow.(CF Section 2.3)
2. Usually we want to work with only a *subset* of your data, to keep only the data in which we are interested.

   - In Stata, the command to keep only variables of interest would be: `keep y x z t`.
   - In R, one option would be to use the subset function: `mysubset <- subset(mydata, select = c(y, x, z, t))`

## 10.4 Reshaping Data From Wide To Long

Usually, we are most interested in reshaping data from *wide* to *long*.

### 10.4.1 Stata

In Stata, I only list variables that vary over time, or are *time varying*. Stata assumes that variables that are *not listed* do *not vary over time*, or are *time invariant*.

Notice also that our *time varying* data are in the *stub-time* format, e.g. `warmth1`, `warmth2`, `physical_punishment1` `physical_punishment2`, etc. Because the variables are named in this way, Stata knows to use the *stub* (e.g. `warmth`) as the variable name, and the numeric value, (e.g. 1, 2, 3) as the timepoint.

> The `id` variable, whatever it is named, has to uniquely identify the observations. A useful Stata command here is `isid`, e.g. `isid id`. If your `id` variable is not unique, it is often due to missing values. `drop if id == .` usually solves the problem (assuming that your `id` variable is indeed named `id`, and not something else).

```
use simulated_multilevel_longitudinal_data_WIDE.dta, clear

describe

reshape long outcome physical_punishment warmth, i(id) j(wave)
```

```
Contains data from simulated_multilevel_longitudinal_data_WIDE.dta
 Observations:         3,000
    Variables:            15                  3 Jul 2024 14:29
-------------------------------------------------------------------------------------------
Variable      Storage   Display    Value
    name         type    format    label      Variable label
-------------------------------------------------------------------------------------------
id              str7    %9s                   unique country family id
physical_puni~1 float   %9.0g                 1 physical_punishment
warmth1         float   %9.0g                 1 warmth
outcome1        float   %9.0g                 1 outcome
physical_puni~2 float   %9.0g                 2 physical_punishment
warmth2         float   %9.0g                 2 warmth
outcome2        float   %9.0g                 2 outcome
physical_puni~3 float   %9.0g                 3 physical_punishment
warmth3         float   %9.0g                 3 warmth
outcome3        float   %9.0g                 3 outcome
country         float   %9.0g                 country id
HDI             float   %9.0g                 Human Development Index
family          float   %9.0g                 family id
identity        float   %9.0g                 hypothetical identity group variable
```

```
intervention    float   %9.0g                 recieved intervention
-------------------------------------------------------------------------------------------
Sorted by: id

(j = 1 2 3)

Data                               Wide   ->   Long
-----------------------------------------------------------------------------
Number of observations            3,000   ->   9,000
Number of variables                  15   ->   10
j variable (3 values)                     ->   wave
xij variables:
             outcome1 outcome2 outcome3   ->   outcome
physical_punishment1 physical_punishment2 physical_punishment3->physical_punishment
                warmth1 warmth2 warmth3   ->   warmth
-----------------------------------------------------------------------------
```

### 10.4.2 R

In R, I only list variables that vary over time, or are *time varying*.

Notice also that our *time varying* data are in the *stub-time* format, e.g. `warmth1`, `warmth2`, `physical_punishment1` `physical_punishment2`, etc. In order to facilitate reshaping the data, it is helpful in R to insert an underscore (_) to separate the *stub* from the *time* variable.

```r
library(dplyr) # data wrangling

library(tidyr) # tidy (reshape data)
```

```r
# rename variables with "_" separator

df <- simulated_multilevel_longitudinal_data_WIDE %>%
  rename(outcome_1 = outcome1,
         outcome_2 = outcome2,
         outcome_3 = outcome3,
         physical_punishment_1 = physical_punishment1,
         physical_punishment_2 = physical_punishment2,
         physical_punishment_3 = physical_punishment3,
         warmth_1 = warmth1,
         warmth_2 = warmth2,
         warmth_3 = warmth3)
```

```r
# pivot_longer() to long data

dfL <- df %>%
  pivot_longer(cols = c(outcome_1,
                        outcome_2,
                        outcome_3,
                        physical_punishment_1,
                        physical_punishment_2,
                        physical_punishment_3,
                        warmth_1,
                        warmth_2,
                        warmth_3),
               names_pattern = "(.+)_(.+)",
               names_to = c(".value", "t"))
```

## 10.5 Data in Long Format

> **Note**
>
> The data below are in *long* format.
> Every individual/family in the data set has a *multiple rows of data*. Every row in the data set is an *individual-timepoint* or *family-timepoint*.

Table 10.4: Data in Long Format

Table 10.4: Table continues below

| country | HDI | family | id | identity | intervention | t |
|---|---|---|---|---|---|---|
| 1 | 69 | 1 | 1.1 | 1 | 0 | 1 |
| 1 | 69 | 1 | 1.1 | 1 | 0 | 2 |
| 1 | 69 | 1 | 1.1 | 1 | 0 | 3 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 1 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 2 |
| 1 | 69 | 2 | 1.2 | 1 | 1 | 3 |

Table 10.5: Data in Long Format

| physical_punishment | warmth | outcome |
|---|---|---|
| 3 | 3 | 57.47 |
| 3 | 4 | 55.06 |
| 1 | 2 | 58.77 |
| 2 | 1 | 50.1 |
| 3 | 0 | 53.31 |
| 3 | 1 | 49.79 |

# 11 Aggregating Data

In many instances, we may wish to aggregate data. For example, we may wish to create *contextual variables* representing the average level of an indicator across a group. In the examples I am using in this book, the group under consideration is the country. Aggregating data is also an important part of discussions of *within* and *between* variation, and is an important part of the correlated random effects model.

In the examples below, I create a group level variable for **warmth**, representing the average level of parental warmth in each country. If warmth is denoted by $\text{warmth}_{ij}$ then the country level variable is denoted by $\overline{warmth}_{.j}$.

Below, I detail the procedure for aggregating data in Stata and R.

### 11.0.1 Stata

#### 11.0.1.1 Get The Data

```
use simulated_multilevel_data.dta
```

#### 11.0.1.2 Create A Group Level Variable

```
bysort country: egen mean_warmth = mean(warmth)
```

### 11.0.2 R

#### 11.0.2.1 Get The Data

```
library(haven)

df <- read_dta("simulated_multilevel_data.dta")
```

#### 11.0.2.2 Create A Group Level Variable

```r
library(dplyr)

df <- df %>%
  group_by(country) %>%
  mutate(mean_warmth = mean(warmth))
```
